CSE231 - Lab 04

Functions, Scope, global, Exam 1

Quick Announcements

Don't post your code publicly on Piazza! If you really need to show all of your code, make it private to the instructors. Make smaller or more generalized questions you have public.

Also, ** congratulations! ** Xeta You've made it to week 4, which means from here on out, the content we'll be covering are all abstractions and supplemental features of programming that make our programs more efficient and organized.

We'll talk about the upcoming midterm after we go through the content, here.

Everyone here has taken calc, right?

Functions are a topic that a lot of new programmers struggle on, but think of them like the functions we know from mathematics!

$$f(x) = 2x+1$$

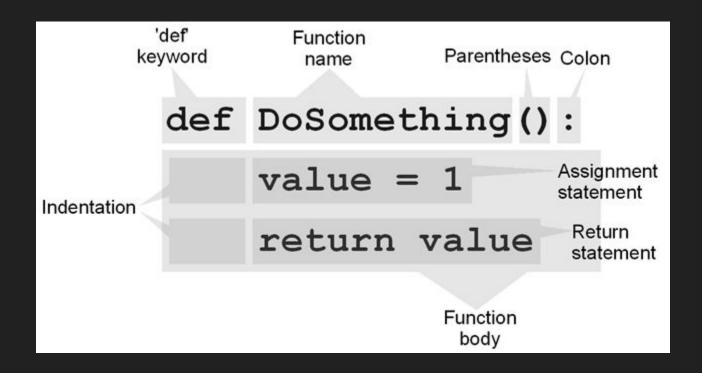

You can think of 'x' as the generalized parameter, where you can plug in any number you want (the domain)

You can think of the number that the function spits back out as the "return" (the range)

$$f(2) = 2(2)+1$$

$$f(2) = 5$$

Function Syntax

Python Translation

Let's take our function from earlier, f(x) = 2x+1, and translate it to Python

```
def f(x):
    return 2*x + 1
```

Simple, right? Again, 'x' is the parameter, it can take on the value of anything we pass into it, and the function will spit back out a different value -- the "return" value.

Same concept to functions in mathematics. In programming however, we can do more than just math in our functions.

Why do we need functions?

For the same reason we don't want to copy-paste chunks of code. Functions offer the ability to *generalize* our code. We can keep the same algorithm in-place, but we can call it with different parameters to perhaps change some calculations or perform different tasks.

It makes code more readable, easier to debug, and highly reusable, especially if you make your functions tight and error-proof.

We've already seen plenty of functions that are included with Python by default, like print() and input(), but now we can make our own.

Scope

What is scope?

Scope can be defined as where the variables you create in your program "exist". When you run a program, Python is constantly destroying variables you aren't using in the background to conserve memory on your computer.

Scope becomes extremely relevant when we're talking about functions. Think of functions as existing in a separate world from the rest of your program. You can give permission to the function to use certain values (the parameters), and it'll send you values back (the return), but neither you nor the function can access each other's stuff directly without that permission. (More about this in a sec)

Local Scope

I have a function, and I want the string I initialized inside of it. Why can I not access it?

```
def my_function():
    my_variable = "Hello, there."
print(my_variable)
```

Like we talked about, things that exist in a function *are for the function*. If you want to obtain a value from it, you would have to take the value from a return.

The variable 'my_variable' is *local* to 'my_function'.

Global Scope

This is where things get tricky. Does this code run?

```
x = 10

def my_function():
    print(x)

my_function()
```

`x` in this case, is considered to be in the *global namespace*, and this is where my "separate world" analogy kinda falls apart.

Global Scope (cont.)

Let's change up our function a little, does this code run now?

```
x = 10

def my_function():
    x += 1

my_function()
```

Spoiler: it doesn't. We are trying to change the variable `x`, we end up getting an UnboundLocalError, meaning Python thinks this variable doesn't exist... so how come we could print it earlier?

Global Scope (cont.)

Variables that are initialized in the *global namespace*, (the space with no indentation), are accessible everywhere in the program, *including the inside of functions*.

However, their value cannot be *changed by a function*. Functions can "look at" these variables, you can copy the value, print it, whatever, as long as you're not changing what the variable holds.

This *does not* go the other way around -- you cannot access variables inside functions in the space outside of them.

What if I need to change a global variable inside my function?

Then you need to pass it into the function as a parameter, and overwrite that name with the function's return. With more practice, it'll become second nature to pass around local variables everywhere.

Do not use the 'global' keyword (bad practice for many reasons)

More on 'global' in a second, what does the first thing mean?

global

I've seen this being used by some people on their projects, and so now is probably a good time to mention to everyone that you're *not allowed* to use it.

There are a multitude of reasons why you shouldn't use 'global', but the biggest really comes down to it being bad practice in the industry. I will dock points if you use it. (Item 9 of the coding standard)

I'm not going to go in-depth because it's not something you should use, but it essentially makes it so that global namespace variables are editable everywhere in the program.

Exam 1

Exam 1 (for this lab) takes place at Anthony Hall, Room 1281. It is on Tuesday, February 4th at 7:00PM. You're allowed a single sheet of paper notes (front and back)!

The exam covers everything up to and including functions.

Dr. Zaabar and I both sent out emails talking more about the exam, please tell me if you didn't receive those emails.

I recently updated my exam 1 notes with more information on scope. If there's anything more you want me to include on there that's whacky, feel free to contact me and I'll add it.

Exam 1 Review Session

There will be a review session for Exam 1 this coming Sunday, February 2nd at 6PM in the Engineering Building, Room 1345.

The session is being held by another TA who is going to go over the Fall 2019 Exam Form A, and will host a Q&A.

Like I said in my emails, review the past exams! It's your best study guide. Get some sleep the night before and stay hydrated.

When you're going over the past exams, generalize the issues you face. E.g. Instead of writing down an entire question onto your note-sheet, write down a sentence or two that explains the *concept* that the question is asking about.
